## DEDICATION

This book is respectfully dedicated to all beer drinkers.

## Acknowledgements

This book would have been impossible without the assistance and co-operation of many institutions, organizations and individuals on both sides of the 'Gardenfence'. My thanks go to my friends Robert Bock, Walter Hodel, Robert J. Ruffle, Don Henry, C. M. Reed, and Peter Schneider, who provided me with information on Soviet helicopters and to the Swiss Military Library in Bern for their kind support. I owe a sincere "Thank You" to the following institutions and organizations:

Smithsonian Institution Library  
P.Z.L. Swidnik  
Aeroflot Office Zurich  
Russian Aviation Research Group of Air Britain  
Div Stutz of ASMZ

Aviaexport Moscow  
Interflug-Industrieflug  
US Department of the Air Force  
Armeemuseum Dresden  
Hannu and Rauni Valtonen of Keski-Suomen Ilmailumuseo

Articles from Eastern European magazines and books contained an unexpected amount of information on Soviet helicopters. Information from the following magazines proved to be very useful for research:

Aviazija i Kosmonautika  
Modellist Konstruktor (Soviet Union)  
Skrzydla Polska  
Flieger Revue  
Volksarmee

Krylja Rodiny  
L+K (Czechoslovakia)  
Zolnierz Polski (Poland)  
Armee Rundschau  
(German Democratic Republic)

I apologize to anyone that I may have forgotten and last but not least I would like to take this opportunity to thank Nick 'The Old Man' Waters III for editing my English into American and for allowing me the extra eight pages needed to make this a more complete and accurate book on the Hind. If my bookkeeping is accurate, it took exactly 124 bottles of beer as well as two bottles of Vodka and two bottles of Swiss Kirschwater to complete this book; my thanks to Brew Masters around the world.

The Mil Mi-24 Hind E assault helicopter armed with a gatling gun, rockets, and four AT-6 Spiral anti-tank missiles has gained a notorious reputation in the West. The Hind has seen combat in Afghanistan, Angola, and Nicaragua and is very effective in the ground support role.

# INTRODUCTION

The Mil Mi-24 Hind\*, has become one of the most widely known assault helicopter gunships in the world. The Hind's impressive firepower and the vast numbers available to the Warsaw Pact are of major concern to NATO planners. The Hind forms the backbone of first line assault helicopter regiments in every Warsaw Pact nation. In the event of war NATO planners estimate Allied forces would encounter hundreds of Hinds over European front lines in the opening stages of a Warsaw Pact armored assault.

The Hind's roots can be traced back to the late 1950s, when the Soviet government issued a requirement for a new transport helicopter to replace the aging Mil Mi-4 Hound. This helicopter was to emerge as the Mi-8 Hip, entering service first with Aeroflot (the Soviet state airline) and later the Soviet Air Force. The Mi-8 Hip was originally designed as a medium lift transport helicopter, however, the aircraft was modified to fill a number of specialized roles, including that of a heavily armed gunship. Mi-8 components were later used as the basis for the Mil Mi-24 Hind, the first dedicated attack helicopter built in the Soviet Union.

The Mi-24 Hind is the Soviets answer to American helicopter gunships such as the Bell AH-1 Huey Cobra and McDonnell-Douglas AH-64 Apache. The Soviets, however, rejected the pure gunship concept popular in the West and designed a new class of helicopter — the assault helicopter. Assault helicopters are capable of both carrying troops into battle and supporting them with devastating firepower. There is currently no western equivalent to the assault helicopter.

## Mikhail L. Mil

Mikhail Leontevich Mil was born on 9 November 1909 in the Soviet city of Irkutsk. In 1926 he entered the Siberian Technological Institute at Tomsk, and later studied at the Aviation Institute in Novotsherkask. In 1929 he helped design the first Soviet autogiro, the KaSKR-1, under the guidance of N.I. Kamov and I.K. Skrishinsky.

Mil graduated from the Novotsherkask Institute in 1931 and joined the Autogiro and Helicopter Department of the Central Aero and Hydrodynamic Institute (TsAGI) in Moscow where he was engaged in research on helicopter aerodynamics. By 1936 he had become an engineer in the helicopter design bureau and later became deputy to the Chief-Designer, Nikolai Kamov.

After the start of the Great Patriotic War (World War II) Mil was appointed Senior Engineer of the First Autogiro Artillery Communications Squadron at Smolensk. This unit was equipped with five TsAGI A-7bis autogiros and flew night operations until deactivated in October of 1941. Two years later Mil returned to the Central Aero and Hydrodynamic Institute and joined the Communist Party of the Soviet Union. During his wartime service he used his engineering background to design improved control systems for the Il-2 *Stormovick* ground attack aircraft and the Il-4 twin engined bomber.

In 1945 Mil received his Doctorate of Technology and by 1947 he had become the Chief Designer of a newly created helicopter experimental design bureau. Over the coming years his helicopter design bureau (helicopter OKB) designed a number of helicopters which set world records for helicopter performance.

Mikhail Mil was much more than a designer and engineer, he was also an excellent pianist and artist. Mil's designs are a mixture of exact mathematic calculations and creative genius. His helicopter designs are said to be born in his sculptor's studio rather than on an engineer's drawing board. His credo as a helicopter designer and Soviet Patriot

Mikhail L. Mil, the Soviet Union's most prominent designer of rotary winged aircraft. Mil's designs include the Mi-1 Hare, Mi-4 Hound, Mi-6 Hook and Mi-8 Hip. Mil died of cancer on 31 December 1970 too early to see the success of his design bureau's latest creation, the Mil Mi-24 Hind.

was simply put: "I would like to build helicopters that help people, accelerate technical progress, and strengthen the Socialist economy. I also want to build helicopters that can defend my native country."

Mil's achievements as a helicopter designer were recognized by a grateful nation and he was awarded the Order of Lenin, Order of the Great Patriotic War, Order of the Red Banner, and the Red Star. In 1966 he received the highest Soviet civilian award, Hero of Socialist Labor.

Mikhail L. Mil died from cancer in Moscow on 31 January 1970. His design bureau was taken over by Marat Tishchenko (designer of the Hind), however, Mil's name will always be associated with the birth, growing pains, and maturity of the Soviet helicopter industry.

*"The names commonly associated with Soviet aircraft and helicopters in the West are not Russian names, but rather those assigned by NATO. To facilitate quick and accurate reporting of Soviet aircraft types, the NATO Air Standards Coordinating Committee assigns a name to each aircraft. Each name has a distinctive sound and also identifies the basic mission of the aircraft. Bombers are all given names beginning with 'B', fighters with 'F', transports with 'C', helicopters 'H' and miscellaneous aircraft are coded with names beginning with 'M'. Additionally propeller driven aircraft carry single syllable names while jet aircraft have multi-syllable names (helicopter names make no distinction between piston and turbine powerplants). Thus the code name Crate (IL-14) indicates a propeller driven transport, while Fishbed (MiG-21) indicates a jet fighter. Variants within a basic design are indicated by a letter suffix, i.e. Hind A through Hind F for the various variants of the Mi-24.*

# Mi-1 Hare

In December of 1947 the Mil Design Bureau (MIL OKB) began development of a light helicopter under the designation GM-1. The prototype made its first flight, with test pilot M.K. Baikalov at the controls, in September of 1948. The GM-1 was powered by a 575 hp Ivchenko AI-26V engine and could carry three passengers. The GM-1 prototype successfully completed testing and was ordered into production under the designation Mi-1. When the aircraft was introduced into Soviet Air Force service NATO assigned it the code name Hare.

The fuselage of the Mi-1 is of tubular steel construction with stressed metal skin and an all metal semi-monocoque tail boom. The rotor blades were made of wood reinforced by a three section tapered tubular steel spar. The Mi-1 gave the Soviets a helicopter with performance equal to or superior to its Western counterparts. The Hare could carry a heavier load faster and higher than its American counterpart, the Sikorsky S-51.

A number of variants of the basic Mi-1 were built. The Mil Mi-1U was a training variant with dual controls. The Mi-1S ambulance carried two gondolas on each side of the fuselage for stretchers. The Mi-1NKh was an agricultural variant used for crop dusting, equipped with spray bars on both sides of the fuselage and chemical tanks capable of holding a total of 500 liters of chemicals. The final production variant of the Hare, the Mi-1 *Moskvich*, was developed in 1961 and featured all metal rotor blades, better sound proofing, hydraulic controls, and improved instrumentation. During the early 1960s trials were conducted with armed variants of the Hare. Anti-tank missile pylons were fitted on both sides of the fuselage, however, the armed Mi-1 was less than successful and was not put into production. Production of the Mi-1 was phased out in the Soviet Union and all jigs and tools were transferred to Poland during 1954. Over 1,700 Mi-1s have been built at the P.Z.L. Factory at Swidnik near Lublin.

The Mi-1 Hare was the first Soviet helicopter put into large scale production. This late production Mi-1M (*Moskvich*) of the para-military DOSAAF — the Voluntary Society for Assistance to the Army, Air Force and Navy was built in Poland.

# Mi-4 Hound

In mid-1951 Joseph Stalin ordered the Soviet helicopter industry to design a twelve passenger helicopter suitable for both civil and military use. He set a strict deadline — one year to design, build, and test fly a prototype. The Mil OKB undertook the project with initial design work beginning in October of 1951. In April of 1952 the first pre-production aircraft (there was no prototype as such) was completed — seven months after Stalin's order.

Powered by an 1,100 hp Shvetsov ASH-62IR radial engine mounted in the nose the helicopter made its first flight a month later with V. Vinitsky at the controls. The first pre-production aircraft had a gross weight of 17,196 pounds, three times larger than the Mi-1. State acceptance trials were successful and during the Summer of 1952 the helicopter was ordered into production under the designation Mi-4. Production Mi-4s were powered by a 1,700 hp ASH-82V engine instead of the 1,100 hp ASH-62IR engine of the pre-production aircraft.

As production increased a number of improvements were made to the Mi-4. The fuselage was reinforced to carry heavier cargos and the rotor blades were redesigned to overcome the blade's tendency to droop and almost strike the airframe. The Mi-4 was publicly shown for the first time at the 1953 Tushino Air Show and shortly afterwards NATO christened the new Soviet helicopter the Hound. In April of 1956 a modified Mi-4 was used to set three world records for helicopter performance.

Mi-4s were developed for both civil and military tasks. The Mi-4P was a ten passenger commercial variant, a Salon variant with accommodation for six passengers in a plush cabin was offered, and an agricultural variant, the Mi-4S, was equipped with a 1,450 liter tank in the fuselage and spray bars on each side of the fuselage.

The military Hound A transport could carry eight to sixteen troops or a jeep sized vehicle. The Mi-4MA Hound B anti-submarine warfare (ASW) variant carried a surface search radar under the nose and MAD gear on the rear fuselage. The Hound C was an airborne communications relay aircraft equipped with multiple receiver and transmitter antennas. Besides being used for military missions Hound Cs were used as radio/TV relay stations for Soviet sporting events.

Transport Hound As were fitted with a single TKB-481 12.7MM machine gun fired by the flight engineer from a gondola under the fuselage. The Soviets used armed Hounds to test and refine vertical assault helicopter tactics. During these early trials a number of Mi-4s were equipped with outrigger pylons on each side of the fuselage for UB-16 rocket pods or anti-tank missiles. The Hound proved unsuitable as a gunship and the armament system was not used operationally, however, the outrigger weapons mounts set the pattern for future Soviet armed helicopters.

An Mi-4 (CCCP-38300) of Aeroflot (Soviet state airline) lands an inspection team on a ranch in Russia. The Hound is Light Gray with a Red cockpit and upper tail boom. The civil registration and Aeroflot logo are in Black. The Hound was the standard Soviet transport helicopter in the late 1950s and early 1960s.

# V-8 (Mi-8) Prototypes

In 1958 the Mil OKB began development of replacements for the highly reliable Mi-1 and Mi-4 series of helicopters. Turbine engines designed specifically for helicopters had become available which offered a number of advantages over the piston engines used in the earlier Mi-1 and Mi-4. The turbine engines were lighter, smaller, and used inexpensive jet fuel instead of expensive high octane gasoline. These advantages led to a decision to replace both the Mi-1 and Mi-4 with new designs of nearly equal size but powered by turbine engines. The Mi-2 Hoplite was the successor to the Mi-1. After production and testing of two prototypes in the Soviet Union, production of the Mi-2 was transferred to Poland where the first Polish-built Mi-2 flew on 4 November 1965.

To replace the Mi-4 Mil proposed a twenty-eight passenger medium lift transport helicopter under the designation V-8\*. The V-8 prototype was a conventional all metal fuselage pod and tail boom helicopter eighty-three feet long (four feet six inches longer than the Mi-4) with an internal cabin volume some 45 percent greater than the Mi-4, increasing usable payload by over 4,000 pounds.

In an effort to reduce development time the rotor hub, rotor and tail boom from an Mi-4 were fitted to the first V-8 prototype. The prototype was powered by a single 2,700 shp (shaft horse power) AI-24V turbine engine\*\* mounted on the upper fuselage above the main cabin. The cockpit was located in the forward portion of the fuselage with side by side seating for the two pilots and provision for a flight engineer's seat mounted between and slightly behind the pilots. Two cockpit doors were installed on either side of the fuselage. Access to main cabin from the cockpit was through a door in the main fuselage bulkhead. The main cabin could hold twenty-four passengers or 8,820 pounds of cargo and was fitted with both a main cabin door on the port side of the fuselage and rear fuselage clamshell cargo doors.

The prototype's fuel system included an internal fuselage tank with a capacity of 254 gallons of jet fuel and provision for two external strap-on tanks. The starboard strap-on tank has a capacity of 388 gallons while the port tank holds 426 gallons. To increase endurance a 521 gallon auxiliary fuel tank can be carried in the cargo compartment. The fuel tanks, engines, reduction gear, and cabin heaters are equipped with automatic fire fighting systems.

The non-retractable tricycle landing gear has a steerable twin wheeled nose mount and low pressure single wheeled main mounts with streamlined wheel covers. The main landing gear is attached to the fuselage underside by two faired 'V' struts with a pneumatic shock strut running from the main mount to the upper fuselage side. A fixed and braced shock absorbing tail skid is installed under the rear of the tail boom.

The prototype V-8 was unveiled to the public at the Tushino Air Show on 9 July 1961. NATO Military Attaches attending the show quickly reported the existence of the new Soviet helicopter and this prototype was assigned the NATO code name Hip A.

To improve the prototypes reliability and flight safety it was decided that the single 2,700 shp engine of the first prototype would be replaced by a pair of coupled 1,500 shp Izotov TV-2-117 turboshaft engines mounted side by side on the second prototype. The second prototype also had newly designed all metal constant chord rotor blades, and a VHF radio blade antenna was installed under the tail boom. The second V-8 prototype flew for the first time on 17 September 1962 with Mil test pilot Koloshenko at the controls. The pilot reported that the prototype handled very well throughout the flight envelope, there was almost no vibration, and cockpit noise levels were greatly improved over earlier helicopters. This prototype was given the NATO code Hip B.

*\*New Mil designs are usually designated 'V' for Vertoljot (Helicopter), during the design and experimental stage. When the aircraft goes into production the designation is changed to 'Mi' denoting a production helicopter of the Mil OKB.*

*\*\*The AI-24V turbine engine was developed by Pavel A. Solovjov, the deputy chief designer of the Shvetsov engine design bureau. Solovjov later became head of the design bureau developing a series of powerplants that were used on other well known Soviet aircraft such as the Mi-6, Mi-10, Tu-134, Il-62 and Il-76.*

The first V-8 prototype used the rotor head, rotor blades, and tail boom from an Mi-4 Hound. The prototype was powered by a single 2,700 shp AI-24V turbine engine.

**V-8 First Prototype  
Hip A**

**V-8 Second Prototype  
Hip B**

The second V-8 Hip prototype was powered by two 1,500 shp Izotov TV-2-117 turboshaft engines instead of the single 2,700 shp Solovjov turbine of the first prototype. The prototype flew for the first time on 17 September 1962 with a four blade main rotor adopted from the Mi-4 Hound.

# Mi-8 Hip

State acceptance trials revealed that a number of changes and improvements were needed before the V-8 could go into production at Kazan and Ulan-Ude. The prototype's four blade rotor system was replaced by a five blade rotor, the cockpit doors were deleted, the VHF radio antenna was relocated to the top of the tail boom, the windows were enlarged, a framed two piece nose cockpit window replaced the smaller single unframed panel, and the windscreen wiper blades were repositioned. Once these changes were incorporated, the V-8 was ordered into production under the designation Mi-8.

Production Mi-8s are powered by two 1,500 shp TV-2-117A turbine engines which are governed by a unique automatic power regulating system. The system regulates engine power through the transmission to the main rotor, governing engine rpm's and guaranteeing equal power from each engine. In the event an engine loses power or fails, the system automatically increases power from the remaining engine. Additionally, the engine controls are equipped with a manual backup system which allows the crew to manually control engine power and rpm's.

The main rotor system is equipped with hydraulic dampers that lessen the effects of ground resonance (vibration) during takeoff, landings, and in a hover. The main rotor consists of five rectangular blades consisting of an aluminum spar and leading edge with honeycomb filled, metal skinned rear sections fastened to the main spar. The main spar is gas pressurized with a loss of pressure warning system that sounds an alarm in case of damage to the blade spar. Both the main and three blade tail rotor are equipped with electrothermal deicing equipment to prevent ice build up on the blades.

Electronics installed on the Mi-8 included: ARK-U2 radio compass, R-860 command radio, RW-3 radio altimeter, ARK-9 radio compass, R-852 and R-842 radios, and an SPU-7 intercom system. A four-channel autopilot is installed that controls the helicopter's roll, yaw, altitude, and course. The autopilot allows the pilot to make inputs or override the autopilot without disengaging the system. The extensive navigation and communications equipment installed on the Mi-8 allows the Hip to operate under all weather conditions and at night.

During the development of the Hip a great deal of attention was given to making the helicopter simple to maintain. Maintenance of the engines, main reduction gear, trans-  
This Aeroflot Mi-8P Hip (CCCP-11052) was the first example shown in the West when it was displayed at the 26th Aerosalon at Le Bourget in 1965. American pilots allowed to fly the aircraft were, according to Soviet sources, quite impressed with the Mi-8's handling qualities and flight characteristics.

A Hip C (Mi-8P) of the People's Republic of China Air Force preparing to depart from a rough concrete helipad is one of at least forty Hips in service with the Chinese Air Force. A number of others are in service with the Civil Aviation Administration of China (CAAC). The overall Light Gray Hip has the serial number painted in Red on the tail boom.

mission, and rotor head can be accomplished in the field without special equipment. For ease of maintenance the engine cowlings and access panels are stressed to serve as work platforms for maintenance personnel. Access to the engine compartment and upper fuselage is made through a hatch in the cockpit roof.

## Mi-8P

The first Mi-8s off the production line were civil models delivered to Aeroflot as commercial twenty-four passenger helicopters under the designation Mi-8P. Aviaexport, the Soviet Foreign Trade Company for aircraft and helicopter sales, offered a variant of the Mi-8P for commercial export with provision for thirty-two seats. Civil passenger variants are equipped with a baggage compartment, toilet facilities, and airstairs installed in the rear clamshell doors. An executive variant, designated the Mi-8S (Salon), was demonstrated at the Paris Air Show in 1971 and could be configured for nine to eleven passengers in a plush interior with a couch, large seats, tables, and a galley.

Crews flying the Hip in operational service pointed out the need for improvements in cabin heat and lateral control. To correct the heating problem the starboard external strap-on fuel tank was fitted with a cabin heater mounted in the forward half of the tank.

## Mi-8T

The success of the Mi-8P led Mil to develop a utility transport variant under the designation Mi-8T. The Mi-8T had the large rectangular cabin windows replaced with

## V-8 Second Prototype Hip B

## Mi-8P Hip C

The vast remote areas of the Soviet Union makes the use of helicopters a necessity. A late production Aeroflot Hip C (Mi-8P) delivers its passengers to a remote area during 1983. The hoist over the cabin door was standard on all late production Mi-8Ps. This Hip is White with the nose and fuselage stripes in Blue. The Aeroflot logo and registration are in Black.

smaller round windows (although a number of early production Mi-8Ts were delivered with rectangular windows), the clamshell rear loading doors were enlarged, hook on ramps for loading vehicles and outsized cargo were provided, and a hoist was mounted on the port side of the fuselage above the rear sliding cabin door.

Further improvements on the Mi-8T included replacing the small 'L' shaped RV-3 radio altimeter transceiver antennas with small round dielectric antennas mounted on the underside of the tail boom and a DIW-1 Doppler radar in a box type fairing was mounted under the forward portion of the tail boom. The Doppler radar allows accurate measurements of drift and airspeed while in a hover or during low speed, low altitude maneuvering. The three pole SRO-2M Odd Rods IFF antennas were relocated from the top of the cockpit to below the fuselage in front of the nose wheel.

Both the MI-8P and MI-8T can be easily converted to an ambulance configuration with a capacity for twelve stretchers and seats for medical personnel.

Military transport variants of the Mi-8T are assigned the NATO code name Hip C. The Hip C is the standard Warsaw Pact transport helicopter and is capable of carrying up to twenty-four fully equipped troops. The circular fuselage windows can be locked in an open position while in flight to allow infantrymen on board to use their weapons.

### Starboard Strap-on Fuel Tank

Hip C (Early)

Hip C (Late)

A pair of Hip Cs (Mi-8P) of the *Luftstreitkräfte der Nationalen Volksarmee* (German Democratic Republic Air Force) in early 1979. The intake for the cabin heater, installed in the forward portion of the strap-on fuel tank, is just below the open cockpit window.

Peru is the sole South American country to use the Hip. Three aircraft were donated by the Soviets after an earthquake in 1970 and were followed by thirty Hip Cs in 1978. This Dark Green over Blue Gray Peruvian Army Hip C, based at Collque-Lima airfield during July of 1985, carries the serial number in White on the tail boom and nose. The fuselage roundel is pierced by a sword with a Silver blade and Yellow hilt.

Interflug-Industrieflug of East Germany operates six Mi-8Ts as flying cranes. An Mi-8T prepares to lift a high voltage mast for the *Deutsche Reichsbahn* (East German railway) in July of 1978. All Interflug Mi-8s have been modified with an observer's station in the main cabin door.

Soviet workers unload crates from the spacious main cabin of an Aeroflot Hip C (CCCP 25886) during 1978. The enlarged rear clamshell cargo doors and Doppler radar housing under the tail boom were introduced on the Mi-8T.

Workers at a coal mine in Siberia board an Mi-8T of the Soviet State Airline Aeroflot, the World's largest airline. An ex-military aircraft, this Hip C retains its military Dark Green over Light Gray color scheme with the Aeroflot lettering in Black over the cabin windows. In any conflict Aeroflot Mi-8s would return to military service.

(Above) One of at least three overall White Hip Cs of the *Polska Lotnicza Eskadra Pomocy Etiopii* (Polish Relief Helicopter Squadron) on a mercy flight over Ethiopia in March of 1985. The aircraft number (641) and 'Polish Relief Helicopter Squadron in Ethiopia' is in Black with the squadron's insignia carried on the fuselage behind the cockpit sliding window.

(Right) The intake plugs of this Earth Brown and Olive Drab camouflaged Hip C are in Red. There is a First Aid kit mounted on the bulkhead behind the pilot's seat. The rescue hoist is standard equipment on all late production Hips.

(Below Right) A Soviet Hip C (Mi-8T), 'Yellow 01' has its cockpit covered with a tarp and the exhausts sealed with metal covers. The upper surface camouflage is Olive Green while the undersurfaces are Light Blue. The two raked antennas on top of the tail boom are VHF radio antennas.

### Doppler Radar Housing

## Armed Variants —Hip C, E, and F

During the mid-1960's the Soviets were closely following US and European armed helicopter experiments and the early American use of armed helicopters in Vietnam. These observations led the Mil OKB to develop an armed variant of the Mi-8. A standard weapons configuration was tested and approved for installation on the Mi-8T. It consisted of bolt-on outriggers capable of mounting two weapons pylons on each side of the fuselage. After a series of successful tests, the armed variant of the Mi-8T was put into production under the Soviet designation Mi-8TB. NATO made no distinction between the transport Hip C and the armed Hip C; both were designated Hip C.

Initial armament carried on the armed Mi-8TB was four UB-16 sixteen shot 57 MM rocket pods. Later these were replaced by larger UB-32 rocket pods each holding thirty-two S-5 shaped charge 57MM rockets. The outrigger pylons can also accommodate bombs up to 550 pounds, gun pods or chemical spray tanks.

### Hip E

Further experiments with helicopter armament led to a more heavily armed variant of the Mi-8, the Mi-8TBK, NATO code name Hip E. The Hip E carried an additional pylon on each fuselage outrigger, four rails for anti-tank missiles mounted above the outrigger pylons, and an Afanasyev 12.7 MM machine gun in the nose. In combat the gun is fired by the flight engineer/gunner sitting between the two pilots. A gyro-stabilized missile control/gunsight is installed over the starboard seat and is operated by the co-pilot. A fully loaded Mi-8TBK carries a total of 192 unguided S-5 rockets (six 32 shot pods) and four AT-2 radio command guided, line of sight anti-tank missiles (NATO code name Swatter) plus the internal gun.

### Hip F

An export variant of the Mi-8TBK was later identified in East Germany and this helicopter received the NATO code name Hip F. It is believed that the German Democratic Republic Air Force is the sole user of this variant. Instead of four AT-2 missiles, the Hip F mounts six AT-3 wire guided anti-tank missiles (NATO code name Sagger) making it the world's most heavily armed gunship helicopter. It is believed that the East Germans modified a number of Mi-8TBKs to the Hip F configuration before the Soviet Union released the improved Swatter (AT-2) missile for export. A fully armed and fueled

An early production Czechoslovakian Air Force Hip C (Mi-8TB) gunship, 'White 0910' has the rotor blades tied down to prevent wind damage while on the ground. The fuselage outrigger pylons are non-standard and were later improved with additional support struts. The IFF antenna on top of the cockpit is covered to protect it during servicing.

A Tan and Medium Green over Light Blue camouflaged Hungarian Air Force Hip C gunship (Mi-8TB) takes off with a load of skydivers during an airshow, at Buda-Örs in the Summer of 1987. The serial number 10427 on the tail boom is in Red with a thin White outline. The fire truck on the left is an East German built Type W-50 fire/rescue truck built by I.F.A.

Mi-8TBK is reportedly very heavy and unresponsive, with little power reserve for maneuverability, especially at low altitudes. Because of the extra weight of the weapons only twelve troops can be carried.

A number of Mi-8 variants have been developed for specialized missions and are known under their NATO code names, including the:

Hip D airborne communications variant with large antennas mounted on the upper and lower tail boom and along the fuselage sides. The Hip D is used for both air-to-air and air-to-ground communications relay.

Hip G Airborne Communications variant with an antenna projecting rearward from the rear of the cabin and additional antennas and a doppler radar mounted on the tail boom.

Hip J electronic counter measures (ECM) variant identified by two small boxes mounted on both sides of the fuselage ahead and behind the main landing gear strut.

Hip K communications jamming electronic warfare variant with a large multiple antenna array on each side of the rear fuselage.

The Mi-8 has become the most widely used helicopter in the Warsaw Pact and figures

Soviet airborne troops deploy from a pair of Hip C gunships (Mi-8TB). The Hip C can carry twenty-eight fully equipped troops or a jeep sized vehicle. A Soviet Assault Helicopter Regiment usually includes a Hip squadron and two Hind squadrons.

The Polish Air Force operates several variants of the Hip. 'White 612' in the foreground is a Hip C gunship (Mi-8TB), while 'White 720' in the background is one of the few Hip C transports (Mi-8P) in Polish service. The open hatch on top of the cockpit is the access hatch to the upper fuselage.

prominently in Soviet/WARPAC tactical exercises and war planning. Some 1,615 Mi-8s are currently in front line service with the helicopter regiments of Soviet Frontal Aviation. The Hip has seen combat in the Middle East, Africa, Asia, and Central America.

Egyptian commandos used a number of Hip Cs and Es in their assault across the Suez Canal during the 1973 Yom Kippur War. Soviet commanders in Ethiopia used the Mi-8 to ferry Cuban and Ethiopian troops behind Somali lines during the Ethiopia/Somalia Ogaden border war. Vietnamese Hips have seen action in Cambodia, while Sandinista Hip Es have been used against Contra Freedom Fighters in Nicaragua. Reports from Afghanistan tell of both Soviet and Afghanistani flown Mi-8s being used both for close air support and chemical warfare during the fighting in that war torn country.

The Mi-8, however, has also been used for more peaceful missions. Three Mi-8s were donated to the Peruvian government following a disastrous earthquake in 1970. The Polish Relief Helicopter Squadron in Ethiopia used three MI-8Ts to fly famine-relief operations during 1985, often working in close cooperation with Western agencies such as the Royal Air Force C-130 Hercules detachment.

A pair of Hip Fs (Mi-8TBK) of the East German Air Force on an exercise in southern East Germany in September of 1980 carry six silver UB-32 rocket pods, however, the missile rails for the Sagger (AT-3) anti-tank missiles are empty. A 12.7MM machine gun is mounted in the nose and fired by the flight engineer.

An armed Hip C gunship (Mi-8TB) of the Hubschraubergeschwader Werner Seelenbinder of the East German Air Force lowers a sling load of cargo during an exercise in October of 1985. The Mi-8 is capable of carrying 6,000 pounds of underslung cargo. The UB-16 rocket pods and aircraft number (7400) on the tail boom are Black.

## Specifications Mil Mi-8TBK Hip E

<b>Main Rotor Diameter</b>	69 feet 10.2 inches
<b>Length</b>	82 feet 9.7 inches
<b>Height</b>	18 feet 6.4 inches
<b>Empty Weight</b>	14,989 pounds
<b>Maximum Weight</b>	26,455 pounds
<b>Powerplants</b>	Two 1,500 shp TV2-117A turboshaft engines
<b>Armament</b>	One nose mounted 12.7mm machine gun. Six pylons for rocket pods or other weapons. Four Swatter (AT-2) anti-tank missiles.
<b>Performance</b>	
<b>Maximum Speed</b>	143 mph
<b>Service ceiling</b>	14,765 feet
<b>Range</b>	311 miles
<b>Crew</b>	Three

A flight of East German Air Force Hip Fs enroute to a landing zone during Exercise Brotherhood in Arms '80 held in September of 1980. The Hip Fs carry silver UB-32 pods, but no AT-3 Swatter missiles. There are at least seventy-five Hip  in service with the *Luftstreitkräfte*.

The Hip F (Mi-8TBK) is the most heavily armed combat helicopter in the world. Fully loaded with six rocket pods, six missiles and a nose mounted machine gun, the Hip F is reportedly unmaneuverable and has demanding flight characteristics. The different shapes of the port and starboard external fuel tanks are due to the installation of a cabin heater in the front of the starboard tank.

Hip Fs of the East German Navy are frequently employed in Search and Rescue operations. The crew of this *Volksmarine* Hip F practice SAR techniques during a training exercise in May of 1982. The Black tactical number 808 identifies this Hip as belonging to a training unit.

Over 8,000 Mi-8s were built before production was phased out in favor of a more powerful variant, the Mi-17 Hip H. A large number of Mi-8s have been exported both commercially and militarily and serve in some forty-two countries including:

Afghanistan	Algeria	Angola	Bangladesh
Bulgaria	China	Cuba	Czechoslovakia
Egypt	Ethiopia	Finland	East Germany
Guinea-Bissau	Guyana	Hungary	India
Iraq	Japan	Kampuchea (Cambodia)	Laos
Libya	Madagascar	Mali	Mongolia
Mozambique	Nicaragua	North Korea	Pakistan
Peru	Poland	Romania	Somalia
Sudan	Syria	Uganda	USA
Vietnam	Yemen	South Yemen	Yugoslavia
Zambia			

Additionally, the Hip was evaluated by British European Airways, although no order was placed and a number of captured ex-Egyptian Hips are believed to be in service with the Israeli Defense Force Air Force for second line duties.

# V-24 Prototype

Published reports of American helicopter combat operations in Vietnam were widely circulated and studied in the Soviet Union. These reports showed that the standard armed troop carrier helicopter, the Bell UH-1 Huey, was too slow, overweight, unresponsive, and too lightly armed to be an effective gunship. These reports also revealed that loss rates for helicopters in combat were much lower than had been expected.

During the Vietnam War the United States lost 2,281 helicopters in combat, however, when compared with the total number of combat hours flown during Vietnam the loss rate averaged one aircraft for every 6,629 hours. This low loss rate was attributed to the US Army's tactics of supporting troop carrier helicopters with gunships, such as the UH-1D Huey gunship and Bell AH-1 Huey Cobra. The gunship proved to be an effective platform for ground support, destroying enemy tanks, as well as convoy escort.

The American study highly influenced Soviet helicopter development and the value of a heavily armed assault helicopter gained favor in Soviet military circles. To Soviet generals the idea of a rotary winged *Stromovick* was highly appealing. In World War II, the heavily armed and armored Ilyushin Il-2 *Stromovick* was highly effective against German armor. A heavily armed and armored helicopter would be of similar value on the modern battlefield, providing ground forces with a mobile platform capable of ground support against enemy troops and armored vehicles unconstrained by terrain or tactical obstructions such as mine fields.

Soviet military doctrine, however, required a helicopter with both a heavy weapons load and the capability of carrying troops. This contrasts sharply with Western design philosophy where troops are not carried by gunships. As a result American, French, and British gunships are smaller, faster, and more maneuverable than their counterparts behind the Iron Curtain.

In 1966 the Soviet Government issued a requirement for a dedicated helicopter gunship to the Mil OKB. Progress on the new gunship design was initially hampered because Mil was heavily engaged in the development of the Mil V-12 Homer, in the event the Homer project was canceled freeing the Mil OKB to concentrate on the gunship project.

The Mil OKB approached the gunship program in a typically Russian manner, using modified components of proven designs. Although derived from the Mi-8, the gunship would be smaller and more powerful. The fuselage was a conventional all metal, semi-monocoque pod and boom structure with retractable landing gear. Two stub wings (similar to those of the Mi-6) were included for weapons pylons and to add lift at high speeds. With a crew of three and eight troops the design had a projected top speed of over 186 mph.

Because Mikhail Mil was terminally ill with cancer (he died on 31 January 1970) the project was placed under the leadership of Marat Tishchenko. The first prototype was completed during 1969 under the designation V-24 and began a series of factory tests. The prototype was powered by two 1,700 shp TV2-117A engines mounted side by side above the main cabin. The crew of three, pilot, navigator, and engineer/gunner were housed under a long greenhouse canopy. Eight troops could be carried in the central cabin which was equipped with large exit doors on each side of the fuselage. The doors were divided horizontally with the upper half opening upward and the lower portion opening downward with a boarding step built in to the lower door half. Four small rectangular windows were installed on either side of the main cabin. These windows, like those on the Mi-8, could be opened in flight and were equipped with gunmounts for AK-47 assault rifles.

The tail boom was faired into the fuselage aft of the cabin and fitted with all moving horizontal stabilizers. The vertical stabilizer housed the tail rotor gear box and drive shaft with the rotor mounted on the starboard side. The five bladed main rotor was of similar configuration to the Mi-8 but smaller in diameter and turned at higher rpms. The

A pre-production V-24 on a test flight during 1971. The V-24 had straight stub wings and four weapons pylons. Western intelligence agencies did not discover the existence of the V-24 until after production Hinds had entered service. The aircraft were given the NATO code name Hind B even though they were actually earlier variants.

oil cooler, rotor mast and auxiliary power unit (APU) were mounted above the engines in a faired housing that gave the appearance of a third engine. The intake for the APU is installed immediately behind the rotor mast with the exhaust on the port side of the fairing.

The strait shoulder mounted stub wings were located above and behind the main cabin. The stub wings provided a twenty-five percent increase in lift during high speed flight, reduced turning radius, and additional space for a pair of weapons pylons on each wing. The wings, however, did cause some loss of performance in a hover by interfering with the rotor downwash. The prototype was fitted with a fully retractable tricycle landing gear. The steerable nose wheel was mounted under the forward fuselage retracting into a bay under the cockpit. The main landing gear rotated ninety degrees, retracting into bays on the fuselage below and behind the main cabin.

During 1971 the first prototype was joined by two pre-production aircraft and these aircraft were used to conduct a series of operational tests. During the test program one aircraft was fitted with a 'fenestron' shrouded tail rotor system, similar to that developed for the Aerospatiale SA 330 Gazelle. The tests proved unsuccessful and the 'fenestron' project was cancelled. Because their existence was not discovered until after appearance of the first production aircraft (Hind A), the prototype and pre-production gunships were given the NATO name Hind B.

After completion of factory and State Acceptance trials the V-24 was approved for production under the designation Mi-24. Production of the gunship was assigned to the State Aircraft Factories at Arsenyev and Rostov with the first production aircraft being delivered to the Soviet Air Force during 1972.

# Mi-24 Hind A

Production Hind As differed from the prototype and pre-production aircraft in a number of ways. The stub wings were completely redesigned with a pronounced anhedral and a flat end plate on the outer wing panel. The end plate also served as a pylon that mounted two missile rails for AT-2 Swatter anti-tank missiles.

This standard Soviet anti-tank weapon (also used on both ground and vehicle mounts) was selected to be the missile armament for the Mi-24. The Swatter is a radio command guided cylindrical missile weighing sixty pounds with a length of 3 feet 9.75 inches. The missile has four small forward control fins and four larger wing fins spanning 2 feet 2 inches mounted on the rear body of the missile. The Swatter has a speed of 335 mph and can hit targets at ranges from 1,640 to 11,500 feet.

To provide guidance for the missiles, an AT-2 missile director pod was mounted under the nose of the Hind A. Other changes to the Hind A included: deletion of the antenna mounted on the top of the vertical stabilizer, installation of a gun camera on the inboard port pylon, redesigned Doppler radar cover, addition of crew boarding steps below the cockpit on the port side, and a short wave aerial was installed under the rear portion of the fuselage.

Extensive communications and navigational electronics are carried on the Hind A. Standard all weather navigational equipment includes: an ARL radio compass, RV-5 radio altimeter, MPR-56P radio beacon receiver, Type SP 50 ILS transceiver, GIK-1 gyro compass, and an RSBN-25 short range navigation system. Communications equipment is equally extensive and includes a Landysk 5 VHF radio, Type Mikron UHF radio, and a Type SPU-7 intercom.

Yellow 36 of the 16th Air Army, Group of Soviet Forces in Germany (GSFG). Hind As were first observed by the West when they deployed to East Germany in 1973. Within a year two Hind A regiments were based at the former Luftwaffe bases of Stendal and Parchim. Early Hind As carried the Odd Rods IFF antenna on the center cockpit canopy frame.

Early Hind As had the tail rotor on the starboard side of the vertical stabilizer. The tail rotor is Black with Red-White-Red warning stripes on the blade tips. Forward view for the pilot is restricted by the gunner and his sighting equipment.

The cockpit floor and crew seats were protected with steel armor plate, however, the canopy was plexiglas rather than armor glass. Fuel tanks were self sealing and filled with an inert gas to prevent fire from crash or battle damage. An external cargo hook could be installed on the fuselage underside allowing the Mi-24 to lift external loads up to 6,000 pounds.

Normal armament carried on the Hind A consisted of four UB-32 thirty-two shot rocket pods, or FAB 250 550 pound high explosive bombs, four Swatter (AT-2) missiles on the stub wing racks, and a single Afanasyev A 12.7MM machine gun on a flexible mount in the center nose section. The gun is operated by the gunner/observer and although on a flexible mount the angle of fire is, however, somewhat limited. Other armament options include UB-16 rocket pods, fuel tanks, and gun pods.

During the Spring of 1973 the first Hind As were deployed to the German Democratic Republic (DDR) as part of the Group of Soviet Forces in Germany (GSFG). By the Spring of 1974 two regiments of forty-five aircraft each were assigned to the 16th Air Army, which is responsible for the capture of Berlin in the event of war. Hind As were based at the GSFG airfields of Parchim and Stendal, both west of Berlin.

The appearance of Hind As in East Germany came as quite a shock for NATO which, at the time, had no helicopter of equal performance and firepower to counter the Mi-24. NATO armor crews reportedly gave the Hind A another name, one that reflected their

White 02, an early Hind A powered by 1,700 hp Izotov TV-117-A engines carries four UB-32 rocket pods on the stub wing pylons. The bulge under the nose is the Swatter missile guidance pod. The Hind A could carry eight fully equipped troops in the center cabin.

impressions of the gunship's impressive firepower, speed, size, and fearsome appearance. NATO tank crews called the Mi-24 the *Bogeyman* — their worst nightmares come true.

The Hind A is not a total *Bogeyman* however — it has its shortcomings. Its large size provides the helicopter a number of built-in tactical disadvantages. Its deep fuselage gives the Hind a high radar signature making it easy to detect and track with radar guided anti-aircraft weapons. Its overall size causes a loss of maneuverability at low speeds and also makes it easy to see and track visually. With a length of some fifty-five feet the Mi-24A is roughly the same size as a World War II medium bomber.

### Hind A (late)

Early production Hind As were powered by the reliable 1,700 shp Izotov TV-2-117A engine. When the more powerful 2,200 shp Izotov TV-3-117 turboshaft engine became available, the engine compartment of the Hind A was redesigned to accept the more

A Hind A provides top cover for a Soviet Army T-62 tank on a powered ferry pontoon during a river crossing exercise. Close co-operation between ground troops and helicopters is practiced during every Warsaw Pact field exercise.

A Hind A of the Soviet Occupation Forces in Afghanistan. The Hind A is used by both the Soviet Air Force and regular Afghan Air Force, however, most were withdrawn from combat after a relatively short period of operations.

powerful engine. The TV-3-117 was also selected to power an advanced variant of the Mi-11 Hip under the designation Mi-17. NATO code name Hip H. The use of the same engine in both the Mi-24 and Mi-17 simplified production and gave Soviet commanders the advantage of being able to use the same spare engine parts for either helicopter.

Besides the engine change the modified Hind A had the tail rotor relocated to the port side of the vertical fin and geared to rotate in the opposite direction. The change from a 'pusher' to a 'puller' configuration improved the helicopter's control responses, particularly in yaw control and eliminated the aerodynamic masking from the vertical stabilizer that had been a problem with the earlier tail rotor system.

Additionally the modified Hind A had the Odd Rods IFF antenna repositioned from the center cockpit frame to the top of the oil cooler intake and also deleted the short wave antenna that had been mounted under the fuselage.

Later in the production run Hind As were modified with the addition of seven external fuselage re-enforcing ribs installed on the port side of the fuselage behind the wing and a modified horizontal stabilizer.

# Specifications Mil Mi-24 Hind A

Main Rotor Diameter	55 feet 9.3 inches
Length	55 feet 11 inches
Height	18 feet 7 inches
Empty Weight	18,519 pounds
Maximum Weight	24,251 pounds
Powerplants	Two 2,200 shp TV3-117 turboshaft engines.
Armament	One 12.7MM nose mounted machine gun. Four Swatter (AT-2) anti-tank missiles. Four pylons for rocket pods, bombs, or other weapons.
Performance	
Maximum Speed	185 mph
Service ceiling	14,765 feet
Range	198 miles
Crew	Three

The landing gear on the Hind A is fully retractable. The nosewheel retracts rearward into a bay under the cockpit while the main gear retracts into wells on the fuselage sides behind the main cabin. The 'L' shaped pitot tubes are carried on both sides of the nose.

The Hind A was exported to three Soviet client states: Algeria, Afghanistan and Libya. Production of the Hind A was phased out during 1975 after some 550 aircraft were built. The Hind A has been withdrawn from Soviet front line combat regiments, however, a number of aircraft remain in service outside the Soviet Union. A dedicated training version was built in small numbers and received the NATO code name Hind C. The Hind C had the nose gun, missile guidance pack, and missile rails deleted, but was otherwise externally identical to the Hind A.

## A-10 Record Aircraft

During 1975 a modified version of the Mi-24 Hind A under the designation A-10, captured eight World Records for helicopter performance and set eleven Soviet National Records. The A-10 was powered by 2,200 shp Izotov TV-2-117A engines and had all armor, armament, and unnecessary equipment removed to save weight. The stub wings, however, were retained since they supported the rotor at high speeds.

These record flights were flown by a female crew. The pilot was Galina Rastorgueva (daughter of the famous Soviet test pilot Victor Rastorgueva) and the navigator was Ludmila Polyanskaya. Both crew members belonged to the civilian Soviet *Valerj Tshkalov* Aeroclub.

The series of record capturing flights began on 16 July 1975. The first record was for speed over a closed course. The A-10 established a new Class E (Helicopter) record when it reached a speed of 212.09 mph over the 15/25 kilometer (9.32/15.54 mile) course. Two days later another record was set for speed over a 100 kilometer closed course (207.82 mph). On 8 August a new helicopter time to climb record was set (9,843 feet in 2 minutes 33.5 seconds). On 13 August the A-10 captured another speed/distance record with a flight of 621.40 miles at an average speed of 206.69 mph. The last Record flight was on 26 August. The A-10 set a new altitude record of 19,685 feet (in 7 minutes 43 seconds).

The drooped wing and end plates with Swatter missile pylons can be seen well from below on this early production Hind A. The rear sliding bulged side window provided the pilot with a degree of downward vision. A gun camera is carried on the upper port inboard pylon.

## Doppler Radar Housing

### V-24 Prototype

The Hind A can carry a variety of weapons on the stub wing pylons. This Hind A carries a mixed load of two UB-32 rocket pods on the inboard pylons and two FAB 250 500 pound high explosive bombs on the outboard pylons.

The Hind A was first sent to Afghanistan in April of 1979, barely eight months before the Soviets 'came to the assistance of the Afghanistan Government', as the Soviet invasion of Afghanistan is reported in the Eastern press.

The crew of a Hind A, pilot, engineer and gunner, head for debriefing after a training mission. Entry to the cockpit is made through the upward opening cockpit side window and rear sliding pilots window on the port side. The 12.7MM machine gun has a limited arc of fire to the side.

### Odd Rods IFF Antenna Locations

A pair of Soviet Air Force Hind As fly in trail formation low over a swollen river. The lead gunship, Yellow 28, is a standard Hind A, while his wingman, Yellow 23, is a late production variant with the seven external stiffening ribs on the port fuselage side.

## External Rib

Hind A (Early)

Hind A (Late)

The late production Hind A was powered by a pair of 2,200 hp TV-3-117 engines. The tail rotor was moved to the port side of the vertical stabilizer to become a 'tractor' rather than a 'pusher' rotor. A similar engine/tail rotor change was made to the Hip under the designation Mi-17 Hip H.

This late production Hind A is displayed as part of the Soviet Air Force Museum at Monino near Moscow. The seven stiffening ribs added to the late production Hind A can be seen behind the White outlined Red star insignia.

# Mi-24 Hind D

Service use of the Hind A by *Frontovaya Aviatsiya* (Frontal Aviation) helicopter regiments quickly showed up a number of needed improvements. Crews complained that the greenhouse cockpit canopy was vulnerable to enemy ground fire, armor protection for both the crew and vital aircraft systems was inadequate, forward vision for the pilot was restricted, and the angle as well as the rate of fire of the 12.7MM machine gun was insufficient. Maintenance personnel reported that rotor blade fatigue life was low and the blades needed to be stronger. These complaints led to a radical redesign of the Hind A.

Mil OKB began work on correcting the Hind A's shortcomings during 1974. Throughout this period the North Vietnamese were providing the Soviets with components from shot down American helicopters. In East Germany a complete rotor system from a Boeing Vertol CH-47 Chinook was put on display as part of an American Vietnam War Equipment exhibit at the Army Museum of the German Democratic Republic in Dresden. Components from the Bell AH-1 Huey Cobra are known to have been evaluated by Soviet engineers. Although it is doubtful that this evaluation had a strong influence on the redesign of the Hind, knowledge of American helicopter technology aided the Soviets greatly in the areas of rotor design, armor, and armament.

Work on the re-designed Hind A was completed in 1975 and when the helicopter first appeared in East Germany during 1976, western observers were surprised by the radical change in appearance of the nose section. NATO assigned the code name Hind D to the variant, even though there was a great deal of argument that this variant should have an entirely new name because the Hind D had the appearance of being a completely new helicopter rather than a re-design of the earlier Hind A.

Although retaining the rotor head, transmission, and basic airframe of the Hind A, the new variant's nose section was completely changed with the pilot and gunner housed in a stepped tandem cockpit with separate canopies for each crewman. The weapons systems operator (WSO) occupied the front cockpit under a hinged starboard opening

Three early Hind Ds at a helicopter field in East Germany during 1976. The open doors on the two nearest aircraft are pilot entry doors. The gunner's canopy is hinged on the starboard side and opens upwards. The three Hind's are painted in identical camouflage patterns of Light Brown, Medium Brown over Light Blue undersurfaces.

The nose wheel of the Hind D has a longer strut than the Hind A to allow sufficient ground clearance for the nose mounted sensor pods. While the Hind A's nose wheel was fully retractable and covered by doors, the Hind D's nose wheel is semi-retractable and is partially exposed when retracted.

canopy while the pilot flew the helicopter from a raised rear cockpit with a large rear hinged automobile style door on the starboard side. Each cockpit canopy is equipped with armored glass and the windshields have individual wiper blades.

The front cockpit of the Hind D is equipped with a second set of flight controls for the weapons systems operator, however, the WSO is usually not a fully trained pilot and their skill in flying the aircraft is limited. A station for a flight engineer is provided in the main cabin, although the engineer is not always carried on operations. The entire nose section is heavily armored with armored seats, anti-fragmentation cockpit lining, and armor glass windshields and canopies. The cockpit of the Hind D provides both the WSO and pilot with excellent all-round visibility.

The redesigned nose incorporates a variety of sensors and weapons aiming equipment mounted in external chin pods. A pod with forward-looking Infrared-Red (FLIR) sensors and low light television (LLTV) equipment is installed on the starboard side. FLIR and LLTV allow the Mi-24 to operate at night and under all weather conditions. The sensor pack on the port side of the nose houses the radar director unit for the Swatter (AT-2) missile system. A long air data sensor probe is fitted to the starboard side of the WSO's canopy frame and incorporates sensors for precision input of air data to the

## COCKPIT Evolution

Hind A  
Three Place  
Cockpit

Hind D  
Two Place  
Cockpit

A deadly duo, a Hip F (Mi-8TBK) and Hind ■ (Mi-24) of the *Adolf von Lützow* Regiment, East German Air Force shortly after take off from an East German base in August of 1981. Warsaw Pact helicopter regiments usually are equipped with both the Hip and Hind.

weapons control and aiming computer. The boom also has an Odd Rods IFF antenna mounted on the attachment fairing just in front of the canopy frame. The fully retractable nose wheel of the Hind A was replaced with a semi-retractable nose wheel with a longer nose wheel strut that increased ground clearance for the nose mounted sensors.

The single 12.7MM machine gun of the Hind A was replaced by a four barrel 12.7MM rotary machine gun capable of firing 800 rounds per minute. The gun is mounted in a turret which can be traversed sixty degrees to either side of the helicopter's centerline. The gun can also be depressed twenty-five degrees and elevated fifteen degrees. The turret gun greatly increases the effectiveness of the helicopter to engage targets without having to maneuver. Ammunition for the gun is limited to 500 rounds. External armament remained the same as that carried on the Hind A.

The Hind D incorporates a number of improvements in communications and navigational radios and radars. A pair of Doppler radar antennas are mounted in a semi-recessed housing under the tail boom, just behind the fuselage fairing. Angled VHF and UHF blade antennas are mounted on top of the tail boom, along with an HF radio antenna with cables running to each stabilizer tip. A short wave communications antenna is mounted under the tail boom behind the Doppler radar housing, followed by two round radio altimeter antennas, and a second Odd Rods IFF antenna array ■ mounted on the underside of the vertical stabilizer. A second HF radio antenna cable is mounted between two posts on the fuselage underside below the main cabin. Small radar warning receiver antennas are mounted on either side of the nose, on the outboard weapons pylons, and wing end plates.

After a short period of operational tests and deployment further improvements were made to the Hind D. The Laser designator pod was repositioned from the port inboard pylon to the tip of the port stub wing, additional low speed precision airflow sensors were fitted on the air data sensor boom and the short wave aerial cable under the tail boom was deleted.

During 1979, the engine air intakes were fitted with vortex dust/debris extractors to prevent engine ingestion of foreign objects during ground operation, takeoff, landing and while in a low hover. During this same timeframe the Soviets changed the tactical markings carried on the Hind D. The unit tactical number, usually the last two digits of the serial number, was repositioned from the nose behind the cockpit to the rear fuselage behind the national insignia.

Warsaw Pact pilots who converted from the Hip (Mi-8) to the Hind (Mi-24) reported that the Hind's cockpit is more cramped than the Hip and there are more instruments and switches to handle. With a shorter control stick the Hind is more sensitive, however, the Hind has better climb, speed, and a greater combat radius. The flight characteristics

The bulge under the fuselage behind the sensor packs on this early production Hind D is the semi-retractable nose wheel. The wires running from the fuselage to the horizontal stabilizers are HF radio antennas. Yellow O7 is camouflaged in Light Brown, Medium Brown upper surfaces over Light Blue undersurfaces.

## Nose Wheel Development

The UB-32 rocket pods on this early Hind D are fitted with a rocket exhaust deflectors on the back of the pod to protect the underside of the stub wing when the rockets are fired. The small downward angled pipe on the fuselage behind the rotor is the Auxiliary Power Unit (APU) exhaust.

of the Hind are more demanding than the Hip, but in the hands of an experienced pilot the gunship is a maneuverable, highly efficient weapons system.

Crew training for the Hind is extensive, especially for the weapons system operator. The Swatter (AT-2) missiles are command radio guided and controlled with a small joy stick in the WSO's cockpit. The missile must be visually tracked to the target requiring a great deal of skill and training to become proficient in guiding the missile.

A senior Soviet officer was recently quoted on the capabilities and mission of the Hind D: *"The attack helicopter will probably have as great an impact in some future war as the tank had in the Great Patriotic War (World War II). The Stromovick helicopter plays an important role in difficult terrain, such as jungles and mountains, and it could prove equally important during fighting in the sprawling cities of Europe and Asia, in fact, anywhere."*

Again using the designation A-10, a modified Hind D was used by the Soviets to capture a World's helicopter speed record. On 21 September 1978 test pilot Gurgen R. Karapetyan flew the A-10 over a 9.32 by 15 by 53 mile closed course at a speed of 228.9 mph. The A-10 (Hind D) was prepared for the record attempt by removing all armament, armor, and pylons.

The Hind D was exported to all Warsaw Pact countries except Romania. For export the gunships are dismantled at the factory and shipped to the country of destination in specially designed crates. Upon arrival the helicopters are re-assembled and test flown by a factory test pilot, before being turned over to their new owners. Unverified reports state that the Soviet Union grants a two year warranty on all aviation equipment exported to Warsaw Pact countries.

The Soviets have continued to improve the Hind D and from 1982 to 1985 a number of changes were noted on service Hind Ds. The UHF aerial mast on the top of the tail boom was redesigned and a chaff/flare dispenser was fitted on the underside of the tail boom near the horizontal stabilizer. Infrared counter measures (IRCM) pulsed jammers were introduced, however, in many cases although the faired platform at the rear of the

A flight of Soviet Air Force Hind Ds prepare to land. The windows on the fuselage side can be locked open in flight and are equipped with mounts for AK-47 assault rifles. The four barreled 12.7MM gatling gun nose turret can engage targets up to sixty degrees on either side.

### Rocket Pod Exhaust Shield

A flight of Polish Air Force Hind Ds, White 15 and 16, during the Spring of 1981. The factory applied camouflage patterns are slightly different, a common feature of Russian built aircraft. Standard factory patterns vary from aircraft to aircraft and colors differ in shade depending on the paint mix.

The strong rotor downwash in a low hover causes debris to be thrown up into the engine intakes. During 1979 the Soviets began fitting Hind Ds with vortex dust/debris extractors to protect the engines. The large engine exhausts produce a high infrared signature making the Hind vulnerable to heat seeking missiles.

### Vortex Dust/Debris Extractors

Hind D (Early)

Hind D

A pair of Soviet Air Force Hind Ds climb out for a training mission. The Hind in the foreground is carrying two Swatter (AT-2) anti-tank guided missiles on the wing end plate pylons.

engine cover fairing was installed the IRCM jammers themselves were not carried. A number of late production Hind Ds have been noted with more tapered and pointed tail rotor blades. The air data sensor boom cover, which prevents damage to the sensors on the ground, was also redesigned.

During 1986 Western analysts detected still further refinements to Hind Ds in Europe. The angle of the exhausts were changed to allow installation of infrared suppression exhaust mixers. To date the IR suppression units have been noted on Hind Ds destined for use in Afghanistan and Nicaragua where the presence of American made Stinger shoulder launched infrared homing anti-aircraft missiles present a serious threat. An unidentified sensor has been added on each side of the nose below the

A Hind D of the Czechoslovakian Air Force takes off as a MiG-23BN Flogger F flies overhead. This Hind carries an enhanced low speed air data boom that supplies precision air speed data to the fire control computer. The Czechs have at least twenty-eight Hind Ds with a number of them based at Plzen-Dobruška close to the West German border.

## APU Exhaust

Hind A

Hind D

weapons operator's cockpit and what is believed to be a tail warning radar antenna was installed on the rear of the vertical stabilizer. Most of these modifications were introduced on the production line at both Arsenyev and Rostov, and kits were produced to allow early production Hind Ds to be retro-fitted with them during major overhauls.

A dedicated trainer variant was also developed for the Hind D. This variant had the nose gun and air data boom deleted and the turret faired over. This training variant of the Hind D is believed to be a pilot trainer without the complex weapons systems, with the forward cockpit used by the instructor while the student sits in the rear cockpit. Student weapons systems operators are trained in standard, fully equipped Hind Ds.

During maintenance the Swatter missile rails, UB-32 pods, nose gun, pitot tubes, and sensor boom are covered. The oil cooler intake cover and Laser designator lens cap are Red with White numbers. The White stripes on the Black main rotor blades are the electrical de-icing system.

Polish maintenance personnel work on the main rotor hub of a Polish Air Force Mi-2 Hoplite while a Hind D is inspected by another crew in the background. The Hind D appears to be relatively new and carries the last two digits of the serial number (1014) in White on the tail boom.

A Mi-8T Hip C of a Soviet Frontal Aviation regiment during 1986. The Hip C is the standard Warsaw Pact medium lift transport helicopter and has been widely exported.

Czechoslovakia

Bulgaria

A Hungarian Air Force Mi-8TB armed Hip C gunship. The Hip C can put twenty-four fully armed troops into a landing zone and support them with up to 128 57MM rockets.

Poland

East Germany

An East German Air Force Mi-8TBK Hip F. With an armament of 192 rockets, six Sagger anti-tank missiles, and an internal 12.7MM machine gun, the Hip F is the worlds most heavily armed assault helicopter.

An early Hind A of the Group of Soviet Forces in Germany during 1974. Early Hind A gunships were powered by 1,700 shp Izotov TV-2-117A engines and had the tail rotor located on the star-board side.

A late production Hind A powered by a pair of 2,200 shp Izotov TV-3-117 engines. The tail rotor has been repositioned to the port side of the stabilizer and seven external reinforcing ribs have been added to the fuselage sides.

Yellow 04, an early production Hind D of a Soviet Assault Helicopter Regiment during 1977. When the Hind D was introduced there were those in NATO who felt the helicopter was a new variant and should have been given a new NATO code name.

A late production Hind of the East German Air Force based at Cottbus Air Base during 1985. Late production Hind D gunships carry a chaff/flare dispenser and an infrared countermeasures jammer for defense against radar and IR guided weapons.

DEFAHR

East Germany

VINYAZI

Hungary

Blue 05, a training Hind D of the Syzran Air Force Academy has had the turret gun and air data boom deleted and the turret opening faired over.

A late production Hind D of the Sandinista (Nicaraguan) Air Force based at Sandino Air Base, Managua during 1986. At least one Sandinista Hind D has been shot down during combat with the Contra Freedom Fighters.

Nicaragua

Yellow 41, an early production Soviet Air Force Hind E during 1978. The Hind E replaced the AT-2 Swatter anti-tank missile with the improved tube launched laser homing AT-6 Spiral anti-tank missile.

A mid-production Hind E carries the 'Excellent Helicopter' award on the fuselage. This award is given to helicopter maintenance crews that meet exacting standards of aircraft maintenance and mission performance. It is the goal of every maintenance crew to earn this award.

An early production Hind F during Exercise 'Friendship-82'. The Hind F had the nose galling gun replaced by a GSh-23 twin barreled revolver cannon mounted on the starboard side. Early Hind F gunships lacked passive defensive equipment (IR jammer, chaff/flare, and engine exhaust units) but are being retro-fitted with this equipment during overhauls.

Soviet

Polish

Polish Hind crews receive last minute instructions before manning their aircraft. During exercises crews often are briefed on the exact location of the 'target' by radio while in the air enroute to the target area. Serial 1015 is believed to have been built in 1979 and was one of the first group of Hinds delivered to Poland.

The enhanced low speed air data boom carries precision airflow sensors that feed information to the Hind's weapons aiming computer. A three pole Odd Rods (SRD-2M) IFF antenna is mounted on the boom attachment point on the canopy frame.

A late production Hind D hovers over its landing pad just after takeoff. The vanes on the air data boom are the low speed sensor that provide precise information on airspeed, side forces, and attitude changes to the fire control computer in the weapons systems operators cockpit.

### Air Data Boom

Hind D (Early)

Hind D

Low Speed Sensor

A Polish Air Force Hind D receives a last minute check prior to take off. The rotors are turning as a mechanic works in the open split doorway of the main compartment. The vehicle in the background is an Ural 375 fuel truck.

A Hind  $\square$  on ground alert waits with the main cabin doors open ready to load a squad of troops. Although the Hind D can carry eight troopers, it is believed that in combat the cabin would be used to carry reloads for the Swatter missile system instead of troops.

The crew of a Hind  $\square$  board their aircraft for another training mission. The laser designator pod on the port wingtip has the protective lens cap installed and is not used for routine flights or training not involving the Swatter missile system.

One of the Hind's principal advantages is that the aircraft can be easily serviced under all conditions. The engine access doors double as maintenance platforms for ground crews. The IFF antenna and air data boom sensors are protected on the ground by coverings painted in Red.

## Cockpit Hatches

A gunship pilot climbs into the cockpit of his Hind D through the heavily armored automobile style door. Both the pilot's and WSO's windshields are equipped with different style windshield wiper blades.

The Flat Black pilot's entrance door on the Hind ■ is heavily armored and has a stowage bag for maps and other important documents. The Silver handle is the door locking handle and behind it is a placard explaining the locking operation.

A Polish weapons systems (WSO) operator in the cockpit of a Polish Air Force Hind D. The missile control sight ■ mounted on the port side of the cockpit. In 1982 crews began receiving the hard flight helmet worn by the WSO, replacing the leather helmet usually worn by helicopter crews in Warsaw Pact countries.

A Swatter (AT-2) missile streaks away from a Hind ■ during live fire training. The solid propellant Swatter is a radio command guided weapon with movable control surfaces on the trailing edges of its rear mounted wings. The WSO steers the missile by keeping the cross-hairs of the missile control unit on the target. The onboard missile director sends the necessary radio signals to the missile to ensure it scores a hit.

**A flight of three Polish Hind Ds prepare to take off. Warsaw Pact tactics call for Hinds to operate in flights of three. The leader normally flies above and behind the two wingmen to spot targets and direct the attack. White 15 is a early production Hind D with the initial UHF aerial mast, while the second gunship, White 78, is equipped with a later UHF aerial mast introduced in 1982.**

An early production Hind D of the Soviet Air Force parked on a helipad in Eastern Europe. The two armored doors of the Low Light Level TV sensor are open. On the ground the Hind's main rotor blades have a distinctive droop if the helicopter is parked for any length of time. The blades are usually tied down to prevent wind damage when the helicopter is secured.

### Forward Looking Infrared/Low Light Level TV Sensor Pod

A Hind undergoing maintenance has the doors of the Forward Looking Infrared (FLIR)/Low Light Level TV (LLTV) sensor open so the system can be calibrated. The open missile director pod is wired into test equipment as the technician checks its operation. The radar antenna itself is covered by a Red protective cover with White numbers.

The doors above the 12.7MM gatling gun turret are the access doors for the ammunition bay. It is believed that the bay holds 500 rounds of belted 12.7MM ammunition. The small box to the right of the gun is the setscrew control for adjusting the boresight of the turret.

### Upper Tail Boom Antennas

Because of the distinctive shape of the double canopies, the Hind D was named *Gorbach* (Hunchback) by its Warsaw Pact crews. The Black areas on the fuselage side and upper stub wing are exhaust stains from the engine exhaust.

A pair of Polish Hind Ds in trail formation during 1981. Swatter anti-tank missiles are usually not carried on routine training missions. Both Hinds are equipped with the later style UHF radio antenna on the top of the tail boom.

White 74 a late production Hind D of the Polish Air Force hovers over its landing site at a Polish airfield. The three Hinds all have minor differences in their camouflage patterns. White 78 is equipped with the later style cross shaped air data sensor cover, while White 13 is fitted with the older round cover.

(Above) A Hind D of the German Democratic Republic Air Force on a training flight over East Germany. Hind Ds of the *Luftstreitkräfte* were first shown to the German public when they took part in a fly-by during the 30th anniversary celebrations of the formation of the German Democratic Republic held in East Berlin on 7 October 1979.

(Below) A late production Hind D of the Czechoslovakian Air Force has the late style UHF antenna. The small dome shaped object behind the raked VHF antenna on the tail boom is the Red anti-collision rotating beacon.

Ground crews perform routine maintenance on a Hind D. The crewman in the foreground is fitting an early style protective cover to the low speed sensors on the air data boom. The time between overhauls on Soviet helicopters is much lower than on their Western counterparts.

A ground crewman has removed the air data sensor cover from the air data boom during a preflight check. This is the late cross shaped sensor cover first introduced in 1982 to replace the earlier round cover that was found to be difficult to use in service. The White number '74' on the Red cover matches the aircraft side number '74'.

A ground crewman opens the starboard engine cover on a late production Hind D. All sensitive equipment: IFF antenna, low speed sensors, pitot tubes, pilot's windshield wiper, and laser designator have been fitted with covers to protect them during servicing and while the aircraft is parked.

## Air Data Boom Sensor Covers

Hind D (Early)

Hind D (Late)

A Polish Air Force Hind D lifts off a fog shrouded airfield in Eastern Europe past a line of Mi-4 Hounds in the background. The nose down attitude of the Hind is typical of a helicopter in transition from vertical to horizontal flight.

An East German Hind D lifts off to escort three Hip Fs (Mi-8TBK) from Cottbus Air Base during an exercise in May of 1981. Black 417 carries an unusual weapons load, a single UB-32 rocket pod on the inboard starboard stub wing pylon. The two small round antennas in front of the tail skid are the transmitter and receiver antennas for the RV-5 radio altimeter.

East German troops camouflage a pair of Hind Ds with netting in a wooded area near the Baltic coast during the Warsaw Pact exercise *Sojuz 81* held in late March of 1981. The canopies have been covered with tarps to prevent sunlight from reflecting off the canopy glass.

A Czech Hind D climbs out of a wooded meadow. The tactical number 0103 is in Black with a thin White outline. The Cyrillic 'Danger' inscription on the lower tail boom is Black on a Yellow background. Czechoslovakia is one of the few Warsaw Pact countries which did not change the Russian warning for one in their own language.

(Above and Below) White 15 and White 76 of the Polish Air Force reveal one of the subtle changes that help identify Hind Ds built in successive production blocks. White 15 is believed to have been produced in 1979 and has the early style UHF antenna on the upper starboard side of the tail boom, while White 76 was produced during late 1982 or early 1983 and has the later style UHF antenna. The camouflage schemes also differ slightly.

A late production Hind D begins a rolling takeoff from a taxiway during an exercise in late August of 1985. The rugged undercarriage of the Hind D allows the aircraft to make short rolling takeoffs when fully loaded with weapons, fuel, and troops.

A Czech Air Force Hind D during a high speed low pass. Everything about the Hind D seems to say — speed. Czech Hinds are reportedly some of the best maintained helicopters in the Warsaw Pact as this very clean Hind D testifies.

A formation of Hind Ds of the Polish Air Force during 1985. White 77 is a 1982 production model with the later style UHF antenna. The second aircraft, White 57, is a late production Hind D with chaff/flare dispenser and IRCM jammer. White 13 is the oldest Hind D, delivered to Poland in 1979. White 58 is also a late production Hind D.

White 58, a late production Hind D of the Polish Air Force carries both the IRCM jammer and chaff/flare dispenser. The chaff/flare dispenser is a strap on unit which is secured to the tail boom between the tail skid and radio altimeter antenna with two metal bands.

### IRCM Jammer

Hind D (Early)

Hind D/E/F

The late style UHF antenna and IRCM jammer platform identify this as a late production Hind D. Although the platform for the IRCM jammer is fitted, the jammer itself is not carried. This is a common practice on late Hind Ds in Warsaw Pact service.

(Above and Below) The weapons system operator and flight engineer check the inboard Swatter (AT-2) missile rack on an East German late production Hind D while other ground crewmen carry ammunition boxes to the waiting Hind. Reloading the weapons systems on any helicopter while the engines are running is a difficult task. The crewman by the open door is plugged into the Hind's intercom and can communicate the progress of the weapons loading to the pilot. The running lights are part of the MLOK-P/R-15 runway lighting system.

A spectator examines the cabin of a Hind D at an airshow in Eastern Europe. The interior of the Hind is painted in Light Gray. The 'U' shaped handles attached to the boarding step are grab handles to help close the door from the inside of the cabin.

## Cabin Door

Closed

Open

(Above) A Hungarian Air Force Hind D carries a chaff/flare dispenser and provision for an infrared countermeasures pulsed jammer. The chaff/flare dispenser was introduced on service Hind Ds during 1985.

(Below) East German troops board a late production Hind D during exercises in 1985. Black 90 is equipped with the later style UHF antenna first introduced in 1982. A chaff/flare dispenser is mounted under the tail boom in front of the tail skid and a mounting platform for an infrared jammer is installed on the rear of the APU fairing.

The strong rotor downwash of the Hind in a low hover was one of the factors that resulted in the introduction of the vortex dust/debris separators on the engine air intakes. The separators do, however, reduce engine airflow by some ten percent lowering available engine power at low speeds.

A Hind D of the Hungarian Air Force carries the chaff/flare dispenser on the underside of the tail boom just in front of the tail skid. Chaff/flares are carried to confuse anti-aircraft radars (chaff) and to decoy infrared homing missiles (flares). These units are being retrofitted to older Hind D's during major overhauls.

The new exhaust stubs were fitted to older Hind D's during regular overhauls. In addition to forcing the exhaust gasses upwards, the new exhausts may be fitted with IR suppression cool air mixers, although these are rarely seen except on Hinds stationed in combat zones.

## Engine Exhausts

Hind D (Early)

Hind D (Late)

(Above) Although equipped with the IRCM jammer platform, the jammer unit itself is not carried on this Hungarian Air Force Hind D. This Hind has been modified with the new exhaust stubs and carries a chaff/flare dispenser on the tail boom. The side number ■ Red outlined with a thin White border.

(Below) This pair of Hind Ds are believed to be two of the first Hinds delivered to Poland in October of 1979. The last two digits of the serial number (1015 and 1016) are carried on the tail boom in White. The Polish Air Force operates three Hind squadrons named *Berezyna*, *Karpaty*, and *Tarcza*.

A Hungarian Air Force Hind D fitted with new sensor pods on the nose under the weapons systems operator's cockpit. Some sources believe that the sensors may be used for helicopter vs helicopter air combat, while others believe that they are associated with a passive infrared system.

### Nose Sensor

Hind D (Late)

This late production Hind D carries two new sensor pods on each side of the nose below the WSO's cockpit. These sensors were first introduced on the Hind during 1985, however, their purpose is yet unknown to Western analysts.

As its ground crew stands by a Hungarian Air Force Hind D prepares to take off. The Hind carries a single UB-32 rocket pod on the outboard wing pylon and an Swatter (AT-2) missile on the inner missile rail. The lower portion of the wing pylons and the UB-32 pod are in Silver-Gray.

### Strap-on Chaff/Flare Dispenser

Hind D (Early)

Hind D (Late)

A late production Hind D fitted with modified upward angled exhaust stubs, nose sensors and chaff/flare dispenser. These modifications are intended to improve the Hind's survivability by reducing the risk from enemy defensive weapons such as radar directed guns and IR homing missiles.

A Soviet ground crewman loads an ammunition belt into the four barreled 12.7MM gatling gun of a Hind D. The four barreled gun can fire 800 rounds per minute. The open door above the crewman's head is the access door for the ammunition bay.

The pilot and the weapon systems operator confer before the start of another mission. The cable dangling from the WSO's leather flight helmet is the SPU-7 intercom plug. The cockpit canopy is operated manually and is hinged on the starboard side. When not in use the canopy support rod is secured to the inside canopy frame.

The pilot of a Soviet Hind performs final checks before taking off for another training mission. The nose wheel of the Hind is fully steerable making the Hind very maneuverable on the ground. The turret gatling gun is at its fully elevated position. The doors above the gun are the ammunition bay loading doors.

This Hind D of the Polish Air Force is equipped with a pulsed infrared countermeasures jammer on a platform at the rear of the APU fairing. The pulsed jammer is one of several modifications designed to lower the Hinds vulnerability to shoulder launched heat seeking missiles such as the US Stinger.

The air data sensor boom has been deleted on this Hind D used in the training role. The Hind pilot training course is reportedly three years long, conducted at both the Saratov Training Center and a school in Central Soviet Asia. The weapon operator's compartment on training Hind Ds is used by the instructor pilot while the student flies the helicopter from the rear (pilots) cockpit.

A formation of trainer Hind Ds of the Syzran Air Force Academy at Saratov. Syzran was the Military Glider Aircraft Pilot's School until 1954 when the school was disestablished and the facility became the Soviet's main training base for rotary winged aircraft. Pilots graduating from the Syzran Air Academy are reportedly among the best trained pilots in the Soviet Air Force.

Training Hind Ds of the Syzran Air Force Academy at Saratov undergo routine maintenance. The nose gun and the ammunition doors have been faired over and the air data sensor boom has been deleted. The majority of training Hinds were converted from standard Hind Ds and Hind Es.

## Trainer Nose

### Hind D (Standard)

### Hind D (Trainer)

# Hind D Export (Mi-25)

It is a common practice for the Soviets to offer a slightly degraded (and cheaper) export variant of their first line combat aircraft and the Hind has been no exception. The export variant of the basic Hind D was developed for export to favored nations outside the Warsaw Pact under the designation Mi-25. The Mi-25 is believed to have degraded sensors and changes in the avionics and other equipment. However, nations within the Warsaw Pact: Bulgaria, Czechoslovakia, East Germany, Hungary, and Poland operate standard Hind Ds. The following countries have received the Mi-25:

Afghanistan	Algeria	Angola
Cuba	Ethiopia	India
Iraq	Cambodia	North Korea
Libya	Nicaragua	Peru
South Yemen	Syria	Yemen
Vietnam		

Additionally two Mi-25s were captured by the Pakistani Army when their Afghan crews defected during late 1985. These aircraft are believed to remain in Pakistan where they have been thoroughly inspected and test flown by both Pakistani and Western aircrews. In April of 1987 Chad captured three Libyan Mi-24s at Wadi Doum, one of these gunships was later reportedly shipped to the United States.

Approximately 2,000 Hind Ds were built before the production of the D was phased out in 1986. Although no longer in production, the Hind D will remain in service for the foreseeable future, as long as the Swatter (AT-2) missile remains a front line Soviet weapon.

A Hind D of the Sandinista Air Force carries both the IRCM jammer and chaff/flare dispenser as protection from Stinger missiles believed to be used by the Nicaraguan Contra rebels. At least one Sandinista Hind is known to have been shot down.

A sharkmouthed Hind D of Grupo Aero 3, Peruvian Air Force. Peru operates a single squadron of Mi-25 Export Hind Ds based at Jorge Chavez Air Base outside Lima.

An Afghan Air Force Hind D carries the tail warning inscription in English. Afghan Hind Ds normally operate in mixed formations with Soviet Hinds, both for training and to ensure the Afghan crews do not defect. During 1985 two Afghan Hinds managed to elude their Soviet wingmen and landed in Pakistan.

A Syrian Air Force Hind D over the Bekaa Valley in Lebanon. The Syrian roundel is carried on the fuselage sides and on the fuselage underside behind the nose wheel bay. The aircraft serial number is in Arabic characters on the tail boom in Black.

# Mi-24 Hind E

To take advantage of the latest developments in anti-tank missile technology the Soviets developed, in parallel with the Swatter (AT-2) missile equipped Hind D, a modified Hind variant to mount the next generation Soviet of anti-tank weapon, the Spiral (AT-6) missile. The Spiral, operationally tested in 1974, is a tube launched, second generation radio command guided anti-tank missile with laser homing in the terminal phase of its flight. The Spiral has higher speed, greater accuracy, longer range, and an improved HEAT warhead. The missile has an effective range of 1,500 feet to approximately three miles. The Spiral is five feet ten inches long and is equipped with folding fins which unfold when the missile leaves the launch tube. The Modified Hind D was test flown during 1976, however, production was limited because of problems in the development of the Spiral missile. Production gradually increased as the Spiral completed its development phase and became an operational weapon in the Soviet inventory.

The Modified Hind D differed from the standard Hind D in armament and sensors. The missile launch rails on the wing end plates were reconfigured to accept Spiral missile tubes, a Spiral missile radar designator pod replaced the Swatter designator pod on the nose and instrument changes were made to the WSO's cockpit. The first Modified Hind Ds were similar to early production standard Hind Ds and lacked the air intake dust/debris separators and were fitted with the early style UHF antenna mast. The enhanced low speed air data boom, however, was carried. The Modified Hind D was first observed by Western analysts in East Germany during late 1979 and received the NATO code name Hind E. The Hind Es were also noted carrying a new sensor housing on the starboard side with an additional blister and aft sliding doors.

Hind Es have been updated with new equipment on approximately the same time scale as the Hind D. IRCM jammer and IR engine suppression units have been added and various communications and navigational equipment upgrades have taken place. During 1985 a change in the armament configuration was introduced on Warsaw Pact Hind Es. The two outboard pylons were equipped with missile racks to carry a pair of Spiral (AT-6) missile tubes in place of the standard UB-32 rocket pods. In this configuration the Hind E can carry a total of eight Spiral (AT-6) missiles.

In 1986, a further modification was noted on the Hind E. Additional sensors were installed on the nose and what is believed to be a tail warning radar was installed on the vertical stabilizer. A fixed landing/search light was installed on the port side close to the nose wheel.

Except for the Spiral (AT-6) missile rails and larger missile director pod, early production Hind Es are almost identical to the Hind D from which it was developed. The Hind E first entered service with the Soviet Air Force in late 1979.

Soviet ground crews service an early production Hind E during the Winter of 1979. The Spiral (AT-6) missile rails on the wing end plate pylons and larger Spiral missile director pod on the port side of the nose are the primary identification features of the Hind E.

## END Plate Missile Rails

Hind D

Hind E

The Hind E retained the gatling gun turret of the Hind D. A Soviet armorer loads belted 12.7MM ammunition into the ammunition bay of an early Hind E. The bay holds approximately 500 rounds of belted ammunition consisting of armor piercing, incendiary and ball rounds.

The Red insignia on the nose of this Hind E is the 'Excellent Helicopter' maintenance award, carried by aircraft meeting strict maintenance standards. The award is presented to maintenance crews by a commission of high ranking officers and political commissars who decide if an aircraft or helicopter meets the exacting standards.

A ground crewman refuels an early production Hind E from a Ural fuel truck, while others inspect the nose wheel and low light TV pod. The engine and transmission access covers have been opened so that the maintenance crew can perform routine inspections of the engine, transmission and rotor head.

## Specifications Mil Mi-24 Hind E

<b>Main Rotor Diameter</b>	55 feet 9.3 inches
<b>Length</b>	55 feet 11 inches
<b>Height</b>	18 feet 7 inches
<b>Empty Weight</b>	18,519 pounds
<b>Maximum Weight</b>	24,251 pounds
<b>Powerplant</b>	Two 2,200 shp TV3-117 turboshaft engines
<b>Armament</b>	One 12.7MM four barreled gatling gun in nose turret. Four to eight Spiral tube launched anti-tank missiles. Four pylons for rocket pods, bombs, or other weapons.
<b>Performance</b>	
<b>Maximum Speed</b>	199 mph
<b>Service ceiling</b>	14,765 feet
<b>Range</b>	466 miles
<b>Crew</b>	Two to Three

Yellow 40, a Soviet Air Force Hind E carries Spiral (AT-6) missile tubes on the wing end plate pylons. The bulge on the nose below the pilot's canopy is a fixed search/landing light.

Hind Es prepare for takeoff on a night training flight with landing lights, position lights, and anti-collision lights brightly lit. The bright light on the nose is the landing light, position lights are mounted on the nose, wing tips, vertical stabilizer and belly. The Red anti-collision beacon is carried on the middle of the upper tail boom just behind the raked VHF antenna.

## Search/Landing Light

Hind D

Hind E/F

### Wing Pylon Spiral Mount

This Polish Hind E includes the latest modifications carried by Warsaw Pact Mi-24s, nose sensor, modified exhaust stubs to accommodate the Infrared Suppression Cool Air Mixers and fixed search/landing light. It is believed that the new exhausts were fitted during the Hind's last major overhaul.

A Hungarian Air Force Hind E flies low over the countryside. This late production Hind E carries all the latest Hind modifications, nose sensors, tail warning radar, chaff/flare dispenser, IRCM jammer, and Spiral missile racks on the outboard wing pylons.

Red 711, a late production Hind E is equipped with a fixed landing/search light on the port side below the nose sensor. In a combat situation the gunship would also be outfitted with infrared engine exhaust suppression shields attached to the engine exhausts.

An early production Soviet Air Force Hind E flies low over the sea. The Hind carries Tan with Medium Green patches on the uppersurfaces over Light Blue undersurfaces, a camouflage scheme common to the Hind E.

A crewman peers out of the open window on the cabin door of Yellow 05, a Soviet Air Force Hind E. The Sprial (AT-6) anti-tank missile is carried in the tubes attached to the wing end plate pylons.

## Tail Sensor

Hind D  
Hind E (Early)

Hind D (Late)  
Hind E (Late)

(Above) A Soviet Hind E during a low pass; the two cabin door windows appear to be open. The fixed search/landing light introduced on the Hind E is located on the lower fuselage just ahead of the nose wheels.

(Below) This late production Hind E carries the latest Hind armament configuration first observed during 1985. The two outboard wing pylons carry racks for Spiral (AT-6) missiles instead of their usual load of UB-32 rocket pods, giving the Hind E/F the capability of carrying a total of eight Spiral anti-tank missiles.

A Hungarian Air Force Hind E, Red 711, conducts a fly-by during an air show at Buda-Örs airfield in 1986. The fuselage side number is in Red with a thin White outline. The national insignia is carried on the fuselage sides and on the belly under the main cabin doors.

# Mi-24 Hind F

In 1982 the Soviets unveiled yet another variant of the Hind during Exercise Friendship 82. The new variant, assigned the NATO code name Hind F, appeared to be a modified Hind E with the nose turret removed and a GSh-23 23MM twin barrel cannon pack fitted to the starboard side of the nose. The twin barrels of the cannon are fitted with prominent flash arresters to prevent the gunner from being blinded when the weapon is fired. The cannon has a rate of fire of 3,400 rounds per minute and a maximum range of 3,300 feet. The weapon is loaded through two doors on the starboard fuselage below the pilot's cockpit door. Although greatly upgrading the Hind's firepower, the fixed cannon installation has one major tactical disadvantage. Unlike the US AH-64 Apache, which has a cannon mounted in a turret, the Hind F must maneuver the whole aircraft to bring the cannon to bear on a target and consequently cannot engage multiple targets simultaneously with its missiles and gun.

The cannon armament does provide the Hind F with the capability of engaging both ground and air targets at a much greater distances than the earlier 12.7MM machine gun, and with far greater striking power. To date the Hind F is believed to be only in service with the Soviet Air Force, but as more Russian regiments are re-equipped with this variant, the aircraft will probably be exported to members of the Warsaw Pact.

The first Hind Fs in operational units carried neither the chaff/flare dispenser or the infrared counter measures jammer. Later, during 1985, these changes were incorporated on the Hind F and aircraft deployed to East Germany were seen with both the chaff/flare dispenser under the tail boom and the IRCM jammer platform on the engine cover fairing. Additionally the Hind F is fitted with a new type of IFF antenna on the nose and tail.

It is believed that the Hind F has the same modifications as the earlier Hind E and can carry at least eight Spiral (AT-6) missiles. If the missile can be carried on all weapons stations, the Hind F is one of the most heavily armed anti-tank helicopters in the World.

The Hind D, E, and F are expected to remain in service with the Soviet Union and Warsaw Pact well into the 1990s. Production (over 3,000 of all variants to date) will continue both to satisfy export customers and Soviet requirements for the foreseeable future, even though the Hind F's successors, the Mi-28 Havoc and Kamov Hokum, will soon be entering service.

The Hind F was first seen by Western observers during the Warsaw Pact exercise Friendship-82. The doors above the GSh-23 23MM cannon pack are the access doors for the cannon's ammunition bay. The small blister on the low light TV sensor housing is only seen on Hind Es and Fs.

Originally given the interim NATO designation Hind E Modified, these Hinds were equipped with twin barreled GSh-23 cannon packs and have been renamed the Hind F. The turret has been removed and the nose has been modified with a smoothly rounded fairing. The Odd Rods IFF antennas on the nose and tail have been replaced by a new style IFF antenna.

An early production Hind A of the Group of Soviet Forces in Germany provides top cover during a river crossing exercise in East Germany during 1975.

A late production Hind D of the Hungarian Air Force files a border patrol over the Hungarian countryside during the Summer of 1987. Hind D gunships are the backbone of the assault helicopter forces of every Warsaw Pact nation.
